Everything you always wanted to know about flat-fielding but were afraid to ask* Richard Crisp 24 January 2012 rdcrisp@earthlink.net www.narrowbandimaging.com

^{*} With apologies to Woody Allen

Outline

- Purpose
- Part 1: Noise
- Part 2: Photon Transfer Analysis: basic concepts (tools we'll use)
- Part 3: Flat Fielding Basic Concepts: what it does, how it works, performance measurement
- Part 4: Making Master Flats: what level of signal, how many exposures
- Part 5: Field Techniques: taking sky flats, qualifying a master flat prior to deployment

Purpose

- The purpose of this material is to teach
 - What flat fielding does
 - How it works
 - How to quantify results
 - Introduction and use of basic camera analysis tools/techniques
 - How to design an optimized flat fielding protocol for your camera

Goals and Methods

- Our goal is to take optimum flats and know they are optimum
- We want to know how many flat frames to shoot and of what signal level
- The approach we'll follow:
 - Characterize camera to measure full well, camera gain, read noise and Photo-Response-Non-Uniformity ("PRNU")
 - Use these parameters to select the signal level for the flat frames and number of frames used for the master
- To do this we will start out with a brief overview of noise followed by a brief overview of photon transfer analysis.

Part 1: Noise

- Image noise sources
- Noise Equation
- Graphical Representation

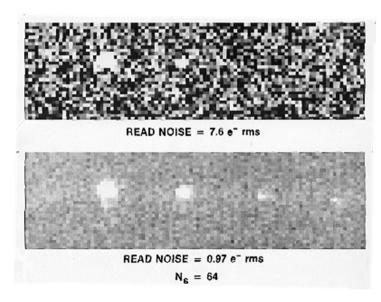

Image Noise Sources

- For an unmodulated image (flat field image), the key noise sources* are
 - Read noise
 - Signal Shot Noise (aka: photon noise, photon shot noise: it will be called Shot Noise or Signal Shot Noise for the remainder of this document)
 - Fixed Pattern Noise
- Depending on signal level any of them can dominate the noise in a single image frame

^{*}neglecting dark signal noise sources which can be managed by cooling

Read Noise

- The read noise is the noise observed in an image when no signal is present
- The noise in a bias frame approximates the read noise
 - zero length exposure
 - no light applied
 - bias frame noise differs from read noise floor by dark signal accumulation during finite readout time
- Read noise can obliterate faint signals

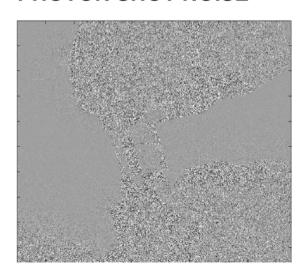

Shot Noise

- The discrete nature of photons results in a variation of the intensity of the incident light as viewed on a photon by photon basis as a function of time
- The variation is the cause of photon shot noise or shot noise as it is also known
- The more intense the image, the greater is the shot noise
- Shot noise is inherent in the image and cannot be avoided and represents the noise floor
- Shot noise in a final image can be eliminated by combining multiple images

IMAGE

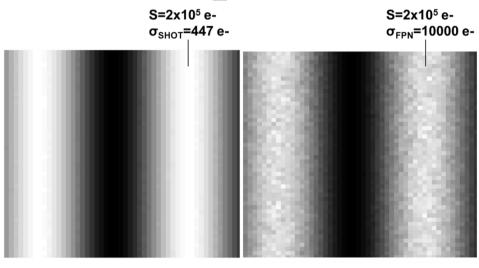

PHOTON SHOT NOISE

Fixed Pattern Noise

- For a flat field exposure, any modulation observed that remains constant from frame to frame is Fixed Pattern Noise (FPN)
- For perfect flat-field illumination of the sensor the FPN observed is caused by variations in the photoresponse of each pixel. This represents the floor of the FPN of the system
- For the camera installed on a practical optical imaging system, variations of light intensity are generally observed
 - Non-uniform light intensity across the frame (ie, "hot centers" or vignetting)
 - Dust motes
 - Filter transmission variations
- These Optical FPN components add to the FPN inherent in the sensor and frequently dominate the overall FPN of the system
- Once FPN dominates the noise of the image, collecting additional signal does not improve the Signal to Noise Ratio (SNR). FPN places an upper limit on the SNR of the system unless removed
- FPN is removed via Flat Fielding (explained later)

Examples of Fixed Pattern Noise

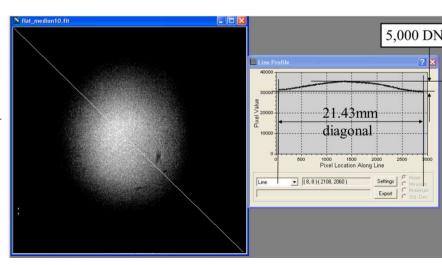

Sensor FPN

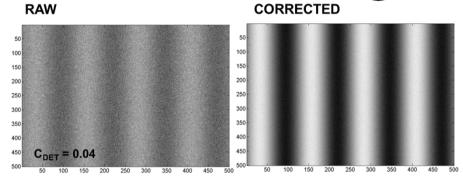

SHOT NOISE

5 % FIXED PATTERN NOISE

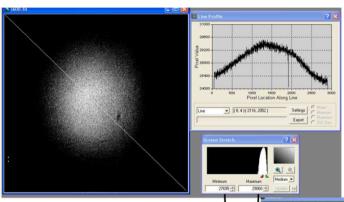

Optical FPN

Flat Fielding for FPN Removal

Sensor FPN removal

More uniform light distribution than measured lens before Flat field: less noise at outer parts of image post/flat field

Optical FPN removal

Tighter range of data values than measured lens in image DN histogram prior to flat field operation

Very tight range of data values in image DN histogram after flat field operation

Noise Equation

- To quantitatively analyze noise it must be described mathematically
- When combining the effects of multiple noise sources that are uncorrelated, quadrature summation is used (square root of the sum of the squares of the noise from each separate source)

Noise Equation*

$$Total_Noise = \sqrt{(read_noise)^2 + (signal_shot_noise)^2 + (fixed_pattern_noise)^2}$$

- Assumptions:
 - Flat field target: no modulation
 - Dark signal sources are negligible

Noise Equation Cont'd

$$Total _Noise = \sqrt{read _noise^2 + signal _shot _noise^2 + fixed _pattern _noise^2}$$

PRNU is Photo-Response-Non-Uniformity (this will be covered in depth later)

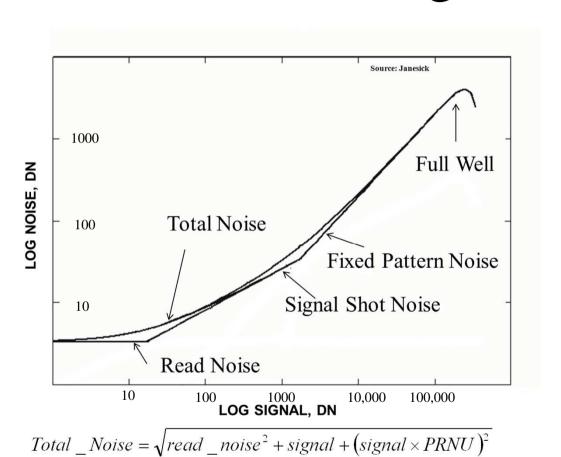

we get:

$$Total _Noise = \sqrt{read _noise^2 + signal + (signal \times PRNU)^2}$$

Graphical Representations

- The noise performance of electronic imaging systems is commonly analyzed using graphical techniques
- Noise is plotted on the Y axis with Signal level plotted on the X axis
- Because the noise and signal may range over several orders of magnitude, it is convenient to use logarithmic axes for the plots to accommodate the large range of data extent

Noise Versus Signal

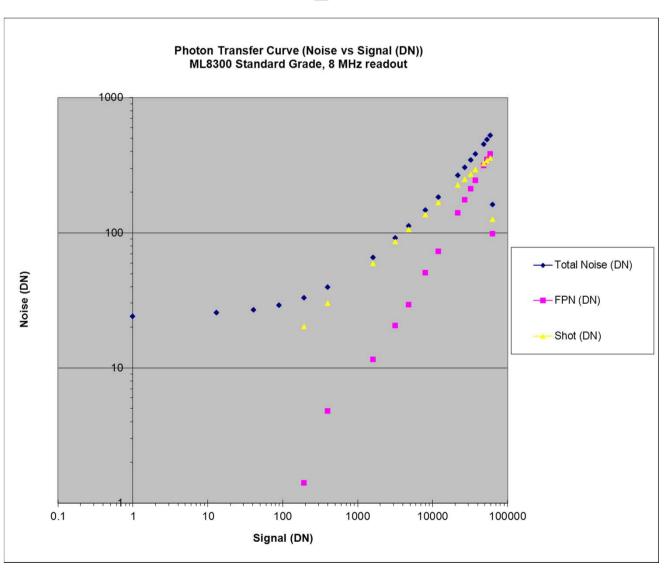

Part 2: Photon Transfer Analysis Basic Concepts (tools we will use)

- Basic PTC and what we learn from it
- How to make a PTC
- Common PTC errors and how to diagnose and fix them
- Other types of PTCs

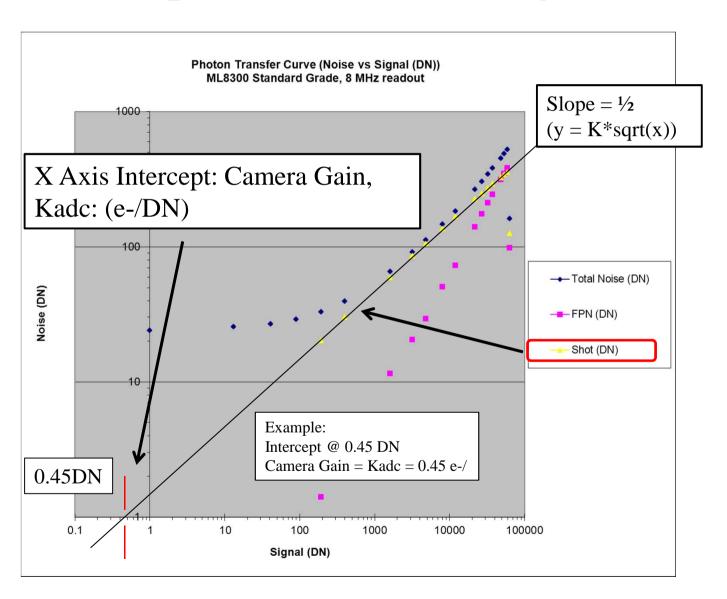

Basic PTC and what we learn from it

- A basic Photon Transfer Curve ("PTC") is a graph of Noise versus Signal measured from a collection of identical pairs of flat-field images of varying signal levels.
 Typically the noise parameters plotted are Total Noise, Fixed Pattern Noise and Shot Noise
- The signal level of the source images used to make the graph span the range from very low signal level to full well
- Each signal level captured is used as a data point for making the graph
- Once the data is plotted in graphical form we can graphically measure
 - Full well
 - Read Noise
 - Camera Gain ("Kadc")
 - PRNU
- We can supplement the PTC with dark frame data and learn the DSNU (Dark Signal Non Uniformity: a measure of how noisy the chip is to assist you in establishing a proper operating temperature: ie using an engineering grade sensor without suffering from excessive noise
- We can also make a separate chart to track linearity by plotting Kadc vs Signal using the same dataset

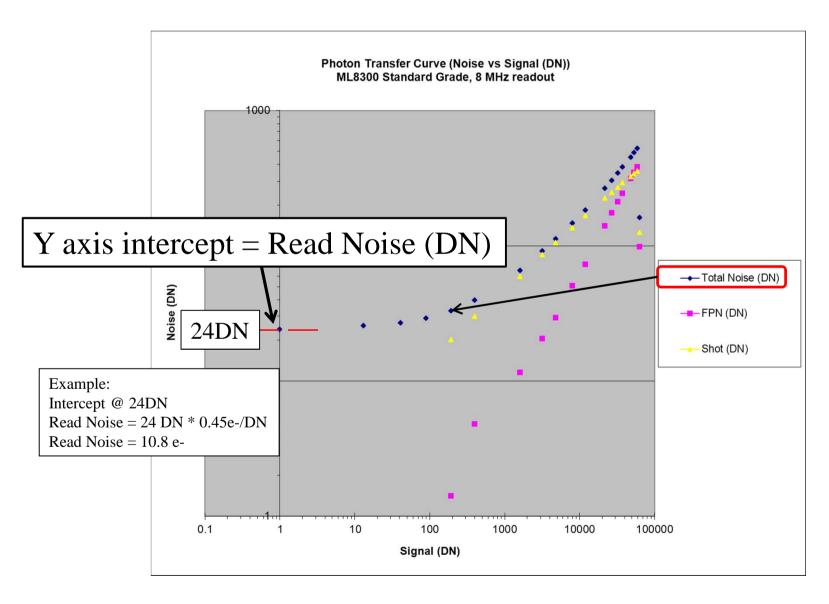

Example PTC

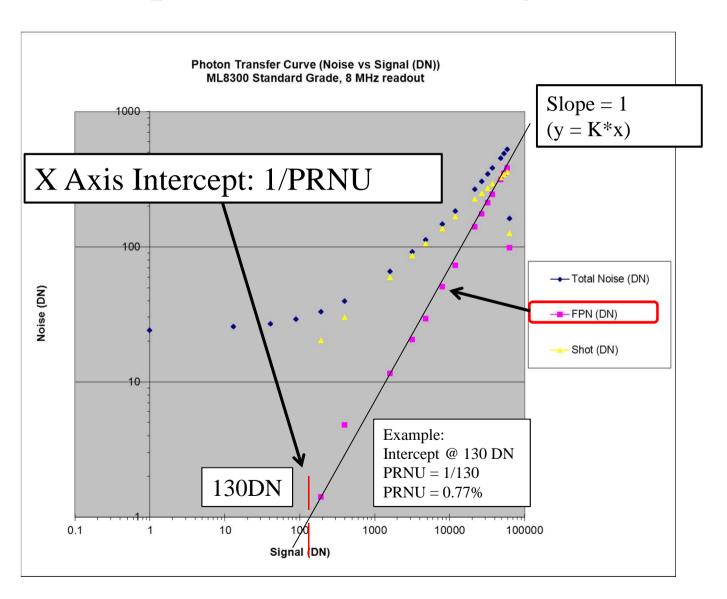

Example PTC: Measuring Gain

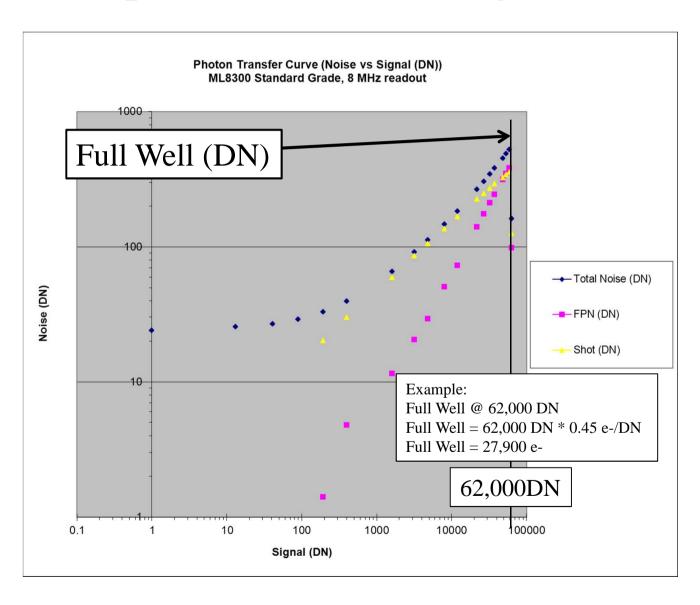

Example PTC: Measuring Read Noise

Example PTC: Measuring PRNU

Example PTC: Measuring Full Well

How to make a PTC

• Data Collection:

- Operate the camera at -25C for the collecting the data below so that dark signal is negligible
- Collect pairs of identical flat field exposures of varying intensity: ranging from nearly dark to fully saturated.
 You can do this inside a house with the bare camera looking at a ceiling in a dimly lit room (preferably adjustable light intensity level)
- Take one bias frame
- Usually about 16-20 flat pairs is sufficient

Reducing the data

- Using Excel or some other spreadsheet program label several columns for recording data
 - Raw Signal, Offset, Standard Deviation, Delta Standard Deviation, Signal Offset, Average Signal Offset,
 Total Noise, Shot + Read, Read(DN), FPN, Shot, Offset Correction
- Recording measurements from the collected data (this is where it gets tedious)
 - Pick analysis region to use for all data: 100 x 100 yields accuracy of 1% (sqrt(#pixels) = accuracy)
 - Crop the bias frame using the size/location chosen above and measure the average signal level and record that into the OFFSET column in the spreadsheet
 - Crop each image within a flat field pair to the analysis region size/location
 - Using the spreadsheet program record the average value of each cropped frame into the Average Signal column and the standard deviation into the Standard Deviation column (measure this using Maxim DL's "Information" window in "Area" mode)
 - Using Pixel Math in Maxim, subtract one cropped region from the other while adding a fixed value of 5000DN to the minuend (to prevent negative numbers).
 - Record the standard deviation of the difference into the Delta Standard Deviation column in the spreadsheet
 - Repeat for each pair of flats

Filling in the Equations

- The next task is to create equations for the remaining columns
- First fill in the value zero into the Offset Correction column. This value may need to be changed after plotting the data
- Use the following equations for the remaining columns (see the next page)

• Signal – Offset:

= (signal – offset – offset correction)

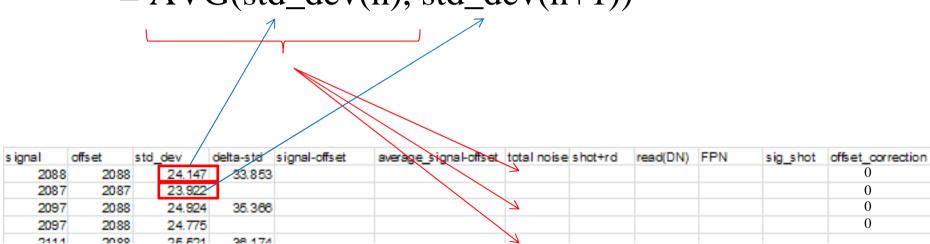

• Average Signal – Offset:

= AVG(signal – offset (n), signal – offset (n+1))

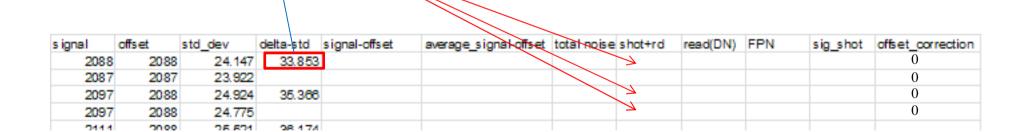

• Total Noise:

= AVG(std_dev(n), std_dev(n+1))

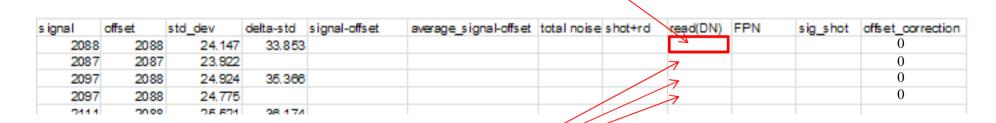

• Shot + Rd:

= delta-std / sqrt(2)

• read:

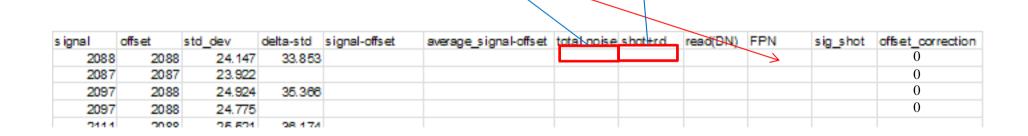

Write in the Y axis intercept value of Total Noise

= Read (n-1) value (recursive from previous row) The value of the read noise will likely be adjusted later to correct a common PTC error

• FPN:

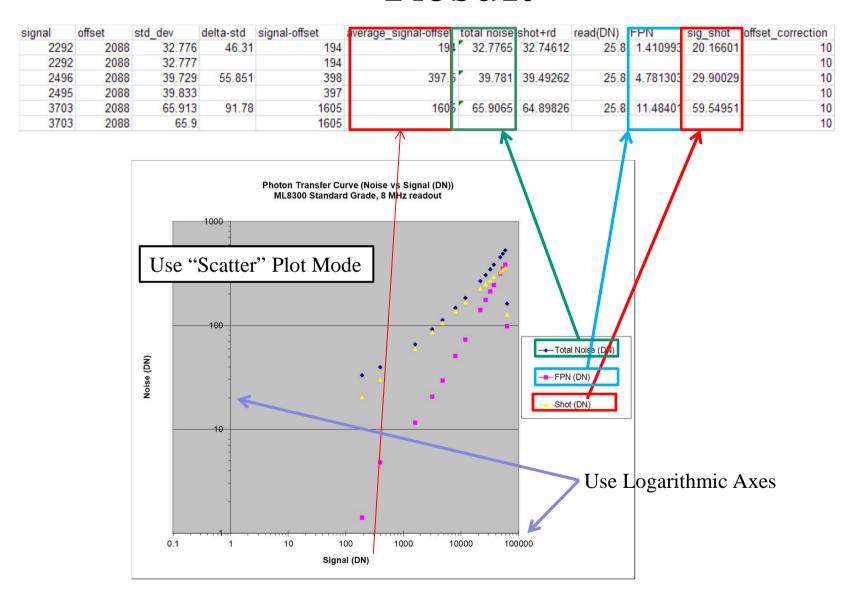

• Sig Shot:

=SQRT(Shot+Read^2 - Read^2)

s ignal	offset	std_dev	delta-std	signal-offset	average_signal-offset	total noise	shot+rd r	ead(DN)	FPN	sig_shot	offset_correction
2088	2088	24.147	33.853							7	0
2087	2087	23.922									0
2097	2088	24.924	35.366								0
2097	2088	24.775									0
2111	20.00	25 521	28 174
